Developer Test

Your task is to write up a webserver in python that will use a mongo database as the backend.

You should have an api that can be called and return the requested data.

There should be 2 endpoints, one for listing the users in the database, and one for retrieving detailed information from a specific user in the database.

The mongo data that should be used will be supplied alongside this test.

To make verification easier, write up a simple script that runs through and calls the endpoints and prints the data that it receives.

This can be a python script with a few lines just to prove the webserver works.

Make sure to record what versions of python and mongo you use, as well as any other information that would be important for running or reviewing the code.
